A CLASS OF DISCONTINUOUS PETROV-GALERKIN METHODS.
PART I: THE TRANSPORT EQUATION

L. DEMKOWICZ AND J. GOPALAKRISHNAN

Abstract. Considering a simple model transport problem, we present a new finite element method. While the new method fits in the class of discontinuous Galerkin (DG) methods, it differs from standard DG and streamline diffusion methods, in that it uses a space of discontinuous trial functions tailored for stability. The new method, unlike the older approaches, yields optimal estimates for the primal variable in both the element size $h$ and polynomial degree $p$, and outperforms the standard upwind DG method.

1. Introduction

We introduce a new Petrov-Galerkin method for advective problems. While it belongs in the class of discontinuous Galerkin (DG) methods, unlike the standard upwind DG method, we are able to prove optimal error estimates in the $L^2(\Omega)$-norm for our discrete solution on general meshes. More importantly, our convergence rates are optimal both in $h$ and $p$ (where, as usual, $h$ is the mesh size and $p$ is the polynomial degree). The method includes a separate outflux approximation on element interfaces and a space of non-standard test functions designed for stability.

The boundary value problem that is the subject of this paper is posed on a polyhedral domain $\Omega$. Given $f$ and $g$, we need to find a finite element approximation to the solution $u$ of

$$\vec{\beta} \cdot \vec{\nabla} u = f$$
on $\Omega$, \quad (1a)

$$u = g$$
on $\partial_{\text{in}} \Omega$, \quad (1b)

Here $\partial_{\text{in}} \Omega$ is defined, letting $\vec{n}$ denote the unit outward normal, by

$$\partial_{\text{in}} \Omega = \{ \vec{x} \in \partial \Omega : \vec{\beta} \cdot \vec{n}(\vec{x}) < 0 \}, \quad (2)$$

i.e., $\partial_{\text{in}} \Omega$ denotes the global inflow boundary. While non-finite-element numerical techniques can be designed for this problem (e.g. the method of characteristics), we aim for finite elements because of its versatility in handling complicated domains as well as certain regular and singular perturbations of the above problem. A regular perturbation of (1) is

$$\vec{\beta} \cdot \vec{\nabla} u + \alpha(\vec{x}) u = f.$$ \quad (3)

A singular perturbation of (1) is obtained by the addition of a small viscosity term with second derivatives. This is harder to analyze. Within the domain of finite element methods for (1), there are two categories, one being the very popular streamline diffusion method [8].

The work of the first author was supported by DOE through Predictive Engineering Science (PECOS) Center at ICES (PI: Bob Moser), and by a research contract with Boeing.

The second author was supported in part by the National Science Foundation under grants 0713833, 0619080, and an Oden fellowship at ICES.
and its descendants, while the other being DG methods. Since our contribution fits in the latter, we shall now review previous works in this category in detail.

The well known first papers proposing and analyzing the original DG method for (1) are [9, 10, 13]. To distinguish this method from our DG method, we will call the original DG method the “upwind DG method” and denote it by UDG, while we call ours the “discontinuous Petrov-Galerkin method” and denote it by DPG. It is proved in [10] that if \( u_h \) is the UDG approximation, then (for a fixed \( p \)) it satisfies

\[
\| u - u_h \|_{L^2(\Omega)} \leq O(h^{p+1})
\]

for some \( s \leq p + 1 \) dictated by the regularity of the exact solution. This result was improved by [9] wherein it was shown that the rate of convergence is in fact \( O(h^{p+1/2}) \). In both cases convergence with respect to \( p \) was not studied. Even if we set aside the \( p \)-convergence issue, notice that both the results are suboptimal in \( h \), as the best approximation error of the finite element space is \( O(h^s) \).

For some special classes of meshes however, many authors have observed (and proved) the optimal rate of convergence of the UDG method [4, 14] with respect to \( h \). Nonetheless, on general meshes, the suboptimal rate of convergence cannot be improved, as shown by a numerical example in [12] using a particular quasiuniform mesh and a smooth exact solution. To express the sentiment of many, we quote from [4] that “the mechanisms that induce the loss of \( h^{1/2} \) in the order of convergence of the \( L^2 \)-norm of the error are not very well known yet”.

An \( hp \) analysis of the UDG scheme was first provided in [2]. They considered the regular perturbation (3) under the assumption that

\[
0 < c_0 \leq \alpha(\bar{x}) \quad \forall \bar{x} \in \Omega
\]

Because of this assumption, they are able to control the \( L^2(\Omega) \)-norm of the solution. They also introduced a stabilization parameter into the original upwind DG method. A few years later, the paper [7] extended the results of [2] in several directions, providing a unified theory for an \( hp \) version of the streamline diffusion method, as well as the upwind DG method. Their analysis did not assume (4), rather they let the advection vector \( \vec{\beta} \) depend on \( \bar{x} \) and assumed

\[
0 < c_0 \leq \frac{1}{2} \nabla \cdot \beta(\bar{x}) + \alpha(\bar{x}) \quad \forall \bar{x} \in \Omega,
\]

as a consequence of which they have stability in \( c_0\|u\|_{L^2(\Omega)} \). (Note that for the case we intend to study (1), the right hand side of (5) evaluates to zero, so (5) does not hold.) Both papers analyzed the stabilized version of the upwind DG method and both relied on the proper choice of the stabilization parameter. While the results of [7] are optimal in \( p \), those of [2] are suboptimal in \( p \). In all these works, the \( L^2(\Omega) \)-rate of convergence of the error with respect to \( h \) remained suboptimal by \( h^{1/2} \). In contrast, our results do not exhibit this suboptimality, nor do we add any stabilization parameter.

The design of our method is guided by a generalization of Céa’s lemma due to Babuška, which we now describe using the following notations (all our spaces are over \( \mathbb{R} \)): Let \( X, X_h \subset X \), and \( V_h \) be Banach spaces and let \( a_h(\cdot, \cdot) \) be a bilinear form on \( X \times V_h \). Suppose the exact solution \( U \in X \) satisfies and the discrete solution \( U_h \in X_h \) satisfies

\[
a_h(U - U_h, v_h) = 0 \quad \text{for all } v_h \in V_h,
\]

If the bilinear form is continuous in the sense that there is a \( C_1 > 0 \) such that

\[
a_h(w, v_h) \leq C_1\|w\|_X\|v_h\|_{V_h} \quad \text{for all } w \in X, \ v_h \in V_h
\]
and also the inf-sup condition, i.e., there is a $C_2 > 0$ such that

$$C_2 \|w_h\|_X \leq \sup_{v_h \in V_h} \frac{a_h(w_h, v_h)}{\|v_h\|_{V_h}} \quad \text{for all } w_h \in X_h, \quad (8)$$

then, as is well known, the following theorem can be formulated:

**Theorem 1.1.** Under the above setting, we have the following error estimate:

$$\|U - U_h\|_X \leq (1 + \frac{C_1}{C_2}) \inf_{w_h \in X_h} \|U - w_h\|_X.$$

**Proof.** The argument is simple and standard:

$$\|U - U_h\|_X = \|U - w_h\|_X + \|w_h - U_h\|_X \leq \|U - w_h\|_X + \frac{1}{C_2} \sup_{v_h \in V_h} \frac{a_h(w_h - U_h, v_h)}{\|v_h\|_{V_h}} \quad \text{by (8),}$$

$$\leq \|U - w_h\|_X + \frac{1}{C_2} \sup_{v_h \in V_h} \frac{a_h(w_h - U, v_h)}{\|v_h\|_{V_h}} \quad \text{by (6),}$$

$$\leq \|U - w_h\|_X + \frac{C_1}{C_2} \|w_h - U\|_X \quad \text{by (7).}$$

This finishes the proof.

Many refinements and improvements of such a theorem are known. But our purpose in going through the above simple argument is to clearly show that the test space need not have approximation properties. Hence, in designing Petrov-Galerkin methods, **while we must choose trial spaces with good approximation properties, we may design test spaces solely to obtain good stability properties.** This will be our guiding principle in designing our method. In fact, the test spaces we propose shortly can have discontinuities inside the mesh elements. We are not the first to consider discontinuous finite elements. Such elements are routinely used in X-FEM and similar methods [1] for difficult simulations like crack propagation. However, we use discontinuities solely for stability purposes, and solely in test spaces. Our trial spaces, being standard polynomial spaces, possess provably good approximation properties.

Our method also introduces a new flux unknown on the element interfaces. This is in line with the recent developments in the field of hybridized DG methods [5], but there are important differences. We will remark on these and on how similar ideas were used in [6, 11] later, after introducing the DPG method (specifically in §2.3).

We organize our presentation such that a spectral version of the method is first exhibited (in Section 2). Details regarding the new space of test functions and the stability estimates for the method on a single element are presented in that section. Section 3 then presents the composite method on a triangular mesh. Optimal $L^2$ error estimates are proved in Theorem 3.2 there. We conclude in Section 5 opining on important future directions. Proofs of a few technical estimates are gathered in Appendix A.

## 2. The Spectral Method on One Element

We start by considering the one-element case to fix the ideas and study the element spaces. In other words, we let $\Omega$ be an $N$-simplex ($N = 2, 3$ are the cases of most practical
importance) which we denote by $K$ throughout this section. We now describe and analyze the DPG method on the single element $K$.

Define the outflow and inflow boundaries of $K$ by
\begin{align}
\partial_{\text{out}} K &= \{ \bar{x} \in \partial K : \vec{\beta} \cdot \bar{n} > 0 \}, \\
\partial_{\text{in}} K &= \{ \bar{x} \in \partial K : \vec{\beta} \cdot \bar{n} < 0 \}.
\end{align}
(9a, 9b)

Here, and throughout the paper, we use $\bar{n}$ to generically denote the unit outward normal on the boundary of a polygonal domain (the domain will vary at different occurrences of $\bar{n}$, but will always be clear from the context, e.g., above it is $K$, while in (2) it was $\Omega$).

2.1. Petrov-Galerkin method using a new test space. Before we describe the method, we need to introduce a new test space. For this, we need a coordinate system aligned with the flow. Let $\bar{e}^{(1)}, \ldots, \bar{e}^{(N)}$, denote the standard unit vectors and let $\bar{e}_\beta$ denote the unit vector in the $\bar{e}_\beta$-direction. Completing $\{\bar{e}_\beta\}$ to form an orthonormal basis $\{\bar{e}_\beta, \bar{e}_\beta^{(2)}, \ldots \bar{e}_\beta^{(N)}\}$ for $\mathbb{R}^N$, we write the new coordinates as $\eta_i$, i.e.,
\[ \bar{x} = x_1 \bar{e}^{(1)} + \cdots + x_N \bar{e}^{(N)} = \eta_1 \bar{e}_\beta + \eta_2 \bar{e}_\beta^{(2)} + \cdots + \eta_N \bar{e}_\beta^{(N)}. \]
(10)

Any function defined on $\partial_{\text{out}} K$ can be extended into $K$ in such a way that the extension is constant along the $\bar{\beta}$-direction, i.e., the extension is independent of $\eta_1$. We call this the extension from outflow boundary and denote it by $E_{\text{out}}$.

Let us consider the question of computing a polynomial approximation of the transport solution $u$ satisfying (1) with $\Omega = K$. The starting point in deriving the DPG method is to multiply (1a) by a test function $v$ and integrate by parts:
\begin{align}
(f, v) &= (\vec{\beta} \cdot \nabla u, v)_K \\
&= -(u, \vec{\beta} \cdot \nabla v)_K + \langle \vec{\beta} \cdot \bar{n} u, v \rangle_{\partial K} \\
&= -(u, \vec{\beta} \cdot \nabla v)_K + \langle \phi, v \rangle_{\partial_{\text{out}} K} + \langle \vec{\beta} \cdot \bar{n} g, v \rangle_{\partial_{\text{in}} K},
\end{align}
(11)

with $\phi = \vec{\beta} \cdot \bar{n} u$ on $\partial_{\text{out}} K$, the outflux variable.

The method finds an approximation to the pair $(u, \phi)$ using the spaces
\begin{align}
M_\ell(\partial_{\text{out}} K) &= \{ \mu : \mu|_F \in P_\ell(F), \text{for all faces } F \text{ of } K \text{ contained in } \partial_{\text{out}} K \}, \\
V_\ell(K) &= \eta_1 P_\ell(K) + E_{\text{out}}(M_{\ell+1}(\partial_{\text{out}} K)).
\end{align}
(12a, 12b)

Here, for any domain $D$, we use $P_\ell(D)$ to denote the space of polynomials of degree at most $\ell$. Note that if $\partial_{\text{out}} K$ consists of a single face of $K$, then $V_\ell(K)$ consists of polynomials, but in general, $V_\ell(K)$ is a non-polynomial space, as it can have lines of discontinuity within $K$.

The spectral DPG method, motivated by (11), defines approximations $(u_p, \phi_{p+1}) \in P_p(K) \times M_{p+1}(\partial_{\text{out}} K)$, satisfying
\begin{align}
-(u_p, \vec{\beta} \cdot \nabla v)_K + \langle \phi_{p+1}, v \rangle_{\partial_{\text{out}} K} &= (f, v)_K - \langle \vec{\beta} \cdot \bar{n} g, v \rangle_{\partial_{\text{in}} K}, \quad \forall v \in V_p(K).
\end{align}
(13)

For compact notation, we write
\begin{align}
\mathcal{A}(u_p, \phi_{p+1}, v) &\triangleq -(u_p, \vec{\beta} \cdot \nabla v)_K + \langle \phi_{p+1}, v \rangle_{\partial_{\text{out}} K}, \\
b(v) &\triangleq (f, v)_K - \langle \vec{\beta} \cdot \bar{n} g, v \rangle_{\partial_{\text{in}} K}, \\
X_p(K) &\triangleq P_p(K) \times M_{p+1}(\partial_{\text{out}} K),
\end{align}
so that (13) can be written as the problem of finding \( (u_p, \phi_{p+1}) \in X_p(K) \) such that

\[
a((u_p, \phi_{p+1}), v) = b(v) \quad \forall v \in V_p(K).
\]

This is a Petrov-Galerkin method because the test and trial spaces are different. The solvability of this method will be clear shortly, as soon as we study the new finite element space.

**Proposition 2.1.** The spaces \( \eta_1 P_p(K) \) and \( E_{\text{out}}(M_{p+1}(\partial_{\text{out}}K)) \) are linearly independent, so that \( V_p(K) \) can be written as the direct sum

\[
V_p(K) = \eta_1 P_p(K) \oplus E_{\text{out}}(M_{p+1}(\partial_{\text{out}}K)).
\]  

**Proof.** Suppose there is an \( r \in P_p(K) \) and \( \mu \in M_{p+1}(\partial_{\text{out}}K) \) such that

\[
\eta_1 r = E_{\text{out}} \mu,
\]

then, letting \( \partial_{\eta_1} \) denote the distributional derivative with respect to the variable \( \eta_1 \), we have

\[
\partial_{\eta_1}(\eta_1 r) = \partial_{\eta_1}(E_{\text{out}} \mu) = 0.
\]

Integrating from the \( \eta_1 = 0 \) plane (extending the polynomial \( r \) to all \( \mathbb{R}^3 \) if necessary) we find that

\[
tr(t, \eta_2, \ldots, \eta_N) = \int_0^t \partial_{\eta_1}(\eta_1 r(\eta_1, \ldots, \eta_N)) \, ds = 0,
\]

for any \( t \), so \( r \equiv 0 \), which in turn implies that \( \mu \equiv 0 \) as well. Thus the sum in (14) is indeed a direct sum. \( \square \)

The degrees of freedom of \( V_p(K) \) can be inferred from the next lemma.

**Lemma 2.1.** Given any \( \mu \) in \( M_{p+1}(\partial_{\text{out}}K) \) and any \( w \) in \( P_p(K) \), there is a unique \( v \) in \( V_p(K) \) satisfying

\[
\begin{align*}
\vec{\beta} \cdot \nabla v &= w, \quad (15a) \\
v|_{\partial_{\text{out}}K} &= \mu. \quad (15b)
\end{align*}
\]

**Proof.** We construct the required \( v \) as a sum of two functions \( v_1 \) and \( v_2 \), defined below. First set

\[
v_1(\eta_1, \ldots, \eta_N) = \int_0^{\eta_1} \frac{1}{|\beta|} w(s, \eta_2, \ldots, \eta_N) \, ds.
\]

Note that \( v_2 \), when restricted to each face of \( \partial_{\text{out}}K \) is a polynomial of degree at most \( p + 1 \). Now let

\[
v_2 = E_{\text{out}}(\mu - v_1|_{\partial_{\text{out}}K}).
\]

It is easy to verify that \( v = v_1 + v_2 \) satisfies both the equalities of (15). The uniqueness of \( v \) is also easy to see: If \( v \) satisfies (15) with \( w = 0 \) and \( \mu = 0 \), then integrating into \( K \) from the outflow boundary along the \( \vec{\beta} \)-direction, we find that \( v \equiv 0 \). \( \square \)

One can now define a new finite element formally in the sense Ciarlet [3] as follows. Let \( \Sigma \) denote the set of linear functionals \( \ell_q, \ell_\eta \) defined by

\[
\begin{align*}
\ell_q(v) &= (\vec{\beta} \cdot \nabla v, q)_K, \quad \text{for all } q \in P_p(K), \\
\ell_\eta(v) &= \langle v, \eta \rangle_F, \quad \text{for all } \eta \in P_p(F), \text{ for all faces } F \subseteq \partial_{\text{out}}K.
\end{align*}
\]
Then, with $\Sigma$ as the set of degrees of freedom (d.o.f), the geometry-space-d.o.f triple $(K, V_p(K), \Sigma)$ defines a unisolvent finite element because of Lemma 2.1. Although $V_p(K)$ may contain discontinuous functions, implementation of this finite element can proceed using standard finite element technology using the above d.o.f.

**Proposition 2.2.** There is a unique solution to the spectral DPG method (13).

*Proof.* The system (13) is square. This follows because the space of trial functions has dimension

$$\dim (X_p(K)) = \dim (P_p(K)) + \dim (M_{p+1}(\partial_{\text{out}} K))$$

$$= \dim (\eta P_p(K)) + \dim (E_{\text{out}} (M_{p+1}(\partial_{\text{out}} K)))$$

which equals the dimension of the test space $V_p(K)$, due to Proposition 2.1.

Hence it suffices to show that if the right hand side of (13) vanishes, the only possible solution is trivial. But this is immediate from Lemma 2.1, by which we may choose $\tilde{V}$ which equals the dimension of the test space $V_p(K)$.

Let us now outline an error analysis. We want to apply Theorem 1.1. The continuity of the form $a(\cdot, \cdot)$ is evident from

$$a((u_p, \phi_{p+1}), v) = -(u_p, \tilde{\beta} \cdot \tilde{\nabla} v)_K + (\phi_{p+1}, v)_{\partial \Omega},$$

$$\leq \|u_p\|_K \|\tilde{\beta} \cdot \tilde{\nabla} v\|_K + h_K^{-1/2} \|\phi_{p+1}\|_{\partial_{\text{out}} K} \|v\|_{\partial_{\text{out}} K}$$

$$\leq \left( \|u_p\|_K^2 + h_K^{-1} \|\phi_{p+1}\|_{\partial_{\text{out}} K}^2 \right)^{1/2} \|v\|_K$$

where we have chosen the norm

$$\|v\|_K = \left( \|\tilde{\beta} \cdot \tilde{\nabla} v\|_K^2 + h_K \|v\|_{\partial_{\text{out}} K}^2 \right)^{1/2}.$$ 

The inf-sup condition also holds, because applying Lemma 2.1, we can find a $v$ such that $-\tilde{\beta} \cdot \tilde{\nabla} v = u_p$ and $v|_{\partial_{\text{out}} K} = h_K^{-1} \phi_{p+1}$, so

$$\sup_{u \in V_p(K)} \frac{a((u_p, \phi_{p+1}), v)}{\|v\|_K} \geq \frac{\|u_p\|_K^2 + h_K^{-1} \|\phi_{p+1}\|_{\partial_{\text{out}} K}^2}{\|v\|_K}$$

$$= \left( \|u_p\|_K^2 + h_K^{-1} \|\phi_{p+1}\|_{\partial_{\text{out}} K}^2 \right)^{1/2} \|v\|_K.$$ 

Thus applying Theorem 1.1, we obtain the following error estimate for the spectral method:

$$\|u - u_p\|_K^2 + h_K^{-1} \|\phi - \phi_{p+1}\|_K^2 \leq 2 \inf_{(u_p, \phi_{p+1}) \in X_p(K)} \left( \|u - u_p\|_K^2 + h_K^{-1} \|\phi - \mu_{p+1}\|_K^2 \right).$$

Here $h_K = \text{diam}(K)$. Reviewing the above argument, the introduction of factors $h_K$ and $h_K^{-1}$ in (16) may seem arbitrary, and indeed it is. While we chose these factors above for simplicity, later we will need to introduce different mesh dependent factors to obtain stability in more appropriate norms.

Although we used the inf-sup condition to motivate the design of our method, the way we used it above does not provide us with the best error estimate possible. It is possible to obtain better error estimates, and indeed to show that the error for each variable is decoupled. In fact, both variables possess superconvergence in the spectral case, as we see next.
Theorem 2.1. Let $\Pi_V$ and $\Pi_M$ denote the $L^2$-orthogonal projections into $P_p(K)$ and $M_{p+1}(\partial_{\text{out}}K)$, respectively. Then
\[
\phi_{p+1} - \Pi_M \phi = 0, \\
u_p - \Pi_W u = 0.
\]

Proof. Subtracting (11) from (13), we find that
\[-(u_p - \Pi_w u, \bar{\beta} \cdot \vec{\nabla} v) + (\phi_{p+1} - \Pi_{\text{out}} \phi, v)_{\partial_{\text{out}}K} = 0
\]
for all $v \in V_p(K)$. By Lemma 2.1, we can choose $v$ in $V_p(K)$ so that $v|_{\partial_{\text{out}}K} = \mathcal{E}_1(\phi_{p+1} - \Pi_{\text{out}} \phi)$ and $\beta \cdot \vec{\nabla} v = \Pi_w u - u_p$. Hence the identities of the theorem follow. \qed

2.2. Local stability estimates. Although our error analysis of the spectral method is already completed (by Theorem 2.1), we want to obtain a few refined stability estimates for the solutions. This will be needed later, when we analyze the multi-element version of the method. To this end, we introduce the following local solution operators:
\[
\Omega_p : L^2(\partial_{\text{in}}K) \mapsto M_{p+1}(\partial_{\text{out}}K), \quad U_p : L^2(\partial_{\text{in}}K) \mapsto P_p(K).
\]
Given $\phi$ in $L^2(\partial_{\text{in}}K)$, the local solutions $\Omega_p \phi$ and $U_p \phi$ are defined by the spectral method (13) with $f = 0$, element by element, as follows:
\[-(U_p \phi, \bar{\beta} \cdot \vec{\nabla} v) + \langle \Omega_p \phi, v \rangle_{\partial_{\text{out}}K} = \langle \phi, v \rangle_{\partial_{\text{in}}K} \quad \forall v \in V_p(K).
\]
Also define solution operators for element sources
\[
\Omega^f_p : L^2(K) \mapsto M_{p+1}(\partial_{\text{out}}K), \quad U^f_p : L^2(K) \mapsto P_p(K)
\]
by
\[-(U^f_p z, \bar{\beta} \cdot \vec{\nabla} v) + \langle \Omega^f_p z, v \rangle_{\partial_{\text{out}}K} = (z, v)_K, \quad \forall v \in V_p(K)
\]
for all $z$ in $L^2(K)$.

The next theorem is the main result of this subsection. Let $h_{\beta,K}$ denote the length of the longest line segment, in the $\bar{\beta}$-direction, contained in $K$, with one endpoint in $\partial_{\text{in}}K$ and the other in $\partial_{\text{out}}K$ (as marked in Fig. 9(b)). We denote by $\vec{n}_F$ a unit normal to a mesh face $F$. For any subcollection $\mathcal{F}_h$ of the set of faces of $K$ where $\bar{\beta} \cdot \vec{n} \neq 0$, we define the following norms:
\[
\|\psi\|^2_{\beta,F,h} = \sum_{F \subseteq \mathcal{F}_h} \frac{1}{|\bar{\beta} \cdot \vec{n}_F|} \|\psi\|_{F}^2,
\]
\[
\|v\|^2_{\beta,F,h} = \sum_{F \subseteq \mathcal{F}_h} |\bar{\beta} \cdot \vec{n}_F| \|v\|_{F}^2.
\]
Here the sums run over all mesh faces $F$ contained in $\mathcal{F}_h$.

Theorem 2.2. The local solution operators have the following stability estimates:
\[
\|\Omega_p \phi\|^2_{\beta,\partial_{\text{out}}K} \leq \|\phi\|^2_{\beta,\partial_{\text{in}}K}, \quad \|U_p \phi\|_{K}^2 \leq \frac{h_{\beta,K}}{|\bar{\beta}|} \|\phi\|^2_{\beta,\partial_{\text{in}}K},
\]
\[
\|\Omega^f_p z\|^2_{\beta,\partial_{\text{out}}K} \leq \frac{h_{\beta,K}}{|\bar{\beta}|} \|z\|_{K}^2, \quad \|U^f_p z\|_{K}^2 \leq \frac{h_{\beta,K}}{|\bar{\beta}|^2} \|z\|_{K}^2,
\]
for all $\phi \in L^2(\partial_{\text{in}}K)$ and $z$ in $L^2(K)$.

A proof of the theorem is given in Appendix A.
2.3. Remarks on the robustness of the outflux variable. Notice that on faces where $\vec{\beta} \cdot \vec{n} = 0$, we have not yet defined any outflux approximation. Since the exact outflux (defined in (26)) vanishes on such faces, we set the discrete outflux $\phi_h$ to zero on those faces.

Computationally, the identification of inflow and outflow faces can only be as accurate as the round-off errors permit, i.e., the strict inequalities (9) can only be implemented up to round-off. This begs the question: On faces $F$ where $\vec{\beta} \cdot \vec{n}_F$ is close to zero, is $\phi_p$ too sensitive to whether we set $F$ to be an inflow or outflow face?

We now argue that it is not. For clarity, consider the situation of Figure 1 (which is entirely typical). The solution $\phi_p$ of (13) can be written as $\phi_p = Q_p g + Q_p^f f$. Then, by the estimates of Theorem 2.2, we have

$$\|\phi_p\|_{\pi, \partial_{\text{out}} K} \leq \|g\|_{\pi, \partial_{\text{in}} K} + \frac{h^{1/2}_{\beta,K}}{|\vec{\beta}|^{1/2}} \|f\|_K.$$ 

This continues to hold as $\vec{\beta} \cdot \vec{n}$ approaches zero on an outflow face (as in Fig. 1). Note that the right hand side remains bounded during this limiting process. But since the left hand side norm contains the factor $|\vec{\beta} \cdot \vec{n}|^{-1/2}$ on the outflow face where $\vec{\beta} \cdot \vec{n}$ approaches zero, the solution $\phi_p$ must approach zero there.

It is this robustness in $\phi_p$ that led us to introduce it as the new ‘outflux variable’ to be solved for. The choice of such a variable is not traditional. In hybridized methods for elliptic problems [5] one usually sets the trace of the ‘primal’ variable $u$ as a new unknown. In this spirit, one could contemplate a method where one finds $u_p$ and $\lambda_p$ satisfying

$$-(u_p, \vec{\beta} \cdot \nabla v)_K + \langle \vec{\beta} \cdot \vec{n} \lambda_p, v \rangle_{\partial_{\text{out}} K} = (f, v)_K - \langle \vec{\beta} \cdot \vec{n} g, v \rangle_{\partial_{\text{in}} K}, \quad (23)$$

instead of (13). Such methods have appeared in the literature – the standard UDG method can be recast into hybrid form with the upwind traces set as a new unknown $\lambda_h$, e.g., the method in [6] for the purely convective case (and more recently in [11]). However, an equation such as (23) can lead to matrices close to singularity in situations like in Figure 1. Indeed, the $\lambda_h$ in (23) cannot be uniquely defined where $\vec{\beta} \cdot \vec{n} = 0$. 

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure1.png}
\caption{A outflow edge degenerating as $\vec{\beta} \to \vec{\beta}_0$}
\end{figure}
3. Approximations using a triangular mesh

In this section, we move to the multi-element case, restricting ourselves to the case of two space dimensions. We consider the composite DPG method on a mesh of the domain $\Omega$, and a general polynomial degree $p$. Since the degree is uniformly set to $p$ on all elements this is the “$p$-version” of the method.

We assume that the domain $\Omega$ is meshed by a geometrically conforming mesh of triangles, denoted by $\mathcal{T}_h$, and set $h = \max\{h_K : K \in \mathcal{T}_h\}$. Define the (discontinuous) finite element spaces

\begin{align}
W_h &= \{w : w|_K \in P_p(K) \text{ for all mesh elements } K \in \mathcal{T}_h\}, \\
M_h &= \{\mu : \mu|_F \in P_{p+1}(F) \text{ for all mesh edges } F \text{ not on } \partial_{in}\Omega\}, \\
V_h &= \{v : v|_K \in V_p(K) \text{ for all mesh elements } K \in \mathcal{T}_h\}.
\end{align}

Here $V_p(K)$ is the new finite element we introduced in Section 2.

3.1. Definition of the composite method. We put together the spectral method on each element to get the following composite method on the mesh $\mathcal{T}_h$: Find $(u_h, \phi_h) \in X_h \stackrel{\text{def}}{=} W_h \times M_h$ satisfying

\begin{equation}
a_h((u_h, \phi_h), v_h) = (f, v_h)_\Omega - \langle \vec{\beta} \cdot \vec{n} g, v_h \rangle_{\partial_{in}\Omega},
\end{equation}

for all $v_h \in V_h$, where

\begin{equation}
a_h((u_h, \phi_h), v_h) = \sum_{K \in \mathcal{T}_h} \left( -(u_h, \vec{\beta} \cdot \nabla v_h)_K + \langle \phi_h, v_h \rangle_{\partial_{out}K} - \langle \phi_h, v_h \rangle_{\partial_{in}K \setminus \partial_{in}\Omega} \right).
\end{equation}

We call $\phi_h$ the \textit{outflux approximation}, because on comparison with (11), we expect it to approximate

\begin{equation}
\phi \stackrel{\text{def}}{=} \vec{\beta} u \cdot \vec{n}_+ \quad (26)
\end{equation}

on every mesh edge $F$, where $\vec{n}_+$ is the unit normal on $F$ with its direction chosen so that $\vec{\beta} \cdot \vec{n}_+ > 0$. On edges where $\vec{\beta} \cdot \vec{n} = 0$, we set $\phi_h = 0$. Equation (11) also shows that this $\phi$ together with the exact solution $u$, satisfies

\begin{equation}
a_h((u, \phi), v) = (f, v)_\Omega - \langle \vec{\beta} \cdot \vec{n} g, v \rangle_{\partial_{in}\Omega},
\end{equation}

for all $v$ in $V = \{v \in L^2(\Omega) : v|_K \in V(K) \text{ for all mesh elements } K\}$, where $V(K)$ is as in (56). In other words, the DPG method is consistent. In order to simplify notation and write $\langle \phi_h, v_h \rangle_{\partial_{out}K}$ for $\langle \phi_h, v_h \rangle_{\partial_{in}K \setminus \partial_{in}\Omega}$, we identify the space $M_h$ with its extension by zero to $\partial_{in}\Omega$, i.e., we identify $M_h$ and $\{\mu : \mu|_F \in P_{p+1}(F) \text{ for all mesh edge } F \text{ and } \mu|_{\partial_{in}\Omega} = 0\}$, to be the same (cf. the definition in (24b)).

3.2. Mesh dependent norms. We collect the definitions of various mesh dependent norms here for ready reference.

First, we extend the definition of the norms $\|v\|_{1,\beta, \mathcal{T}_h}$ and $\|v\|_{\beta, \mathcal{T}_h}$ to more general collections $\mathcal{T}_h$ of edges from the entire mesh (now not necessarily edges of one triangle) simply by letting the sums in (19) and (20) runs over all such edges in $\mathcal{T}_h$. As before, only edges
with $\vec{\beta} \cdot \vec{n} \neq 0$ are picked. Using these extended definitions, we now define more norms on a subcollection of mesh elements $\mathcal{R}_h$, as follows:

$$\|v\|_{h,\beta,\mathcal{R}_h}^2 = \sum_{K \in \mathcal{R}_h} h_{\beta,K} \|v\|_{\beta,\partial_{\text{out}}K}^2,$$

$$\|\psi\|_{h,\frac{1}{2},\mathcal{R}_h}^2 = \sum_{K \in \mathcal{R}_h} h_{\beta,K} \|\psi\|_{\frac{1}{2},\partial_{\text{out}}K}^2,$$

$$\|\psi\|_{h,1,\mathcal{R}_h}^2 = \sum_{K \in \mathcal{R}_h} \frac{1}{h_{\beta,K}} \|\psi\|_{1,\partial_{\text{out}}K}^2,$$

$$\|\psi\|_{h,\frac{1}{2},\mathcal{R}_h}^2 = \|\psi - \mathcal{Q}_p \psi\|_{\frac{1}{2},\mathcal{R}_h}^2.$$

The norm on the trial space is defined by

$$\|(u, \phi)\|_{h}^2 = \sum_{K \in \mathcal{T}_h} \left(\|u - U_{hp}\|_{K}^2 + \|\phi - \mathcal{Q}_p \phi\|_{1,\beta,K}^2\right).$$

The norm on the test space is defined by

$$\|v\|_{h}^2 = \sum_{K \in \mathcal{R}_h} \|\vec{\beta} \cdot \vec{n}_{\partial_{\text{out}}K} v\|_{K}^2 + \|v\|_{h,\beta,K}^2.$$

It is obvious from the construction of $V_p(K)$ that the above is a norm on $V_h$. To show that $\|(u, \phi)\|_h$ is a norm on the test space, we first need to recall the following.

**Lemma 3.1.** In any triangulation $\mathcal{T}_h$ of $\Omega$, there is at least one triangle $K \in \mathcal{T}_h$ such that $\partial_{\text{in}}K \subseteq \partial_{\text{in}}\Omega$.

**Proof.** See [10]. \(\square\)

**Proposition 3.1.** The functional $\|(u, \phi)\|_h$ is a norm on the space $X = L^2(\Omega) \times M$, where $M = \{\mu : \mu|_F \in L^2(F) \text{ for all mesh edges } F \text{ and } \mu|_{\partial_{\text{out}\Omega}} = 0\}$.

**Proof.** Suppose $\|(u, \phi)\|_h = 0$. Then, in particular

$$\|\phi - \mathcal{Q}_p \phi\|_{\beta,\partial_{\text{out}}K} = 0$$

for all elements $K$. By Lemma 3.1, there is an element $K$ with $\partial_{\text{in}}K \subseteq \partial_{\text{in}}\Omega$. On this element, $\phi|_{\partial_{\text{in}}K} = 0$, so $\mathcal{Q}_p \phi|_{\partial_{\text{out}}K} = 0$. Hence (33) implies that $\phi|_{\partial_{\text{out}}K} = 0$. Proceeding inductively over all elements we find that $\phi = 0$. This in turn implies that $u - U_{hp} \phi = u = 0$. \(\square\)

### 3.3. Preliminary error analysis

It is possible to get stability and error estimates for the DPG method in the mesh dependent norm immediately. Solvability of the method follows as a particular consequence.

**Theorem 3.1.** The bilinear form $a_h(\cdot,\cdot)$ satisfies the inf-sup and continuity conditions:

$$\sup_{v_h \in V_h} \frac{a_h((u_h, \phi_h), v_h)}{\|v_h\|_h} \geq \|(u_h, \phi_h)\|_h, \quad \forall u_h \in W_h, \phi_h \in M_h,$$

$$a_h((u, \phi), v_h) \leq \|(u, \phi)\|_h \|v_h\|_h, \quad \forall u \in L^2(\Omega), \phi \in M, v_h \in V_h.$$
If \((u, \phi)\) and \((u_h, \phi_h)\) are the exact and discrete solutions, then
\[
\| (u - u_h, \phi - \phi_h) \|_h^2 \leq 2 \inf_{(w_h, \mu_h) \in W_h \times M_h} \| (u - w_h, \phi - \mu_h) \|_h^2.
\]

**Proof.** We first rewrite (25) using the definition of the local solution operators in (17) as follows:
\[
a_h((u_h, \phi_h), v_h) = \sum_{K \in \mathcal{T}_h} \left( - (u_h, \vec{\beta} \cdot \vec{\nabla} v_h)_K + \langle \phi_h, v_h \rangle_{\partial_K} \right) - \sum_{K \in \mathcal{T}_h} \langle \phi_h, v_h \rangle_{\partial_K} - \sum_{K \in \mathcal{T}_h} \langle \phi_h, v_h \rangle_{\partial_{\text{out}K}}
\]
\[
= \sum_{K \in \mathcal{T}_h} \left( - (u_h - U_p \phi_h, \vec{\beta} \cdot \vec{\nabla} v_h)_K + \langle \phi_h - Q_p \phi_h, v_h \rangle_{\partial_{\text{out}K}} \right).
\]

Let us prove the inf-sup condition. By Lemma 2.1, we can choose \(v_h\) element by element, such that
\[
-\vec{\beta} \cdot \vec{\nabla} v_h |_{\partial_K} = u_h - U_p(\phi_h) |_{\partial_K}, \quad v_h |_{\partial_{\text{out}K}} = \frac{\langle \phi_h - Q_p(\phi_h) |_{\partial_{\text{out}K}} \rangle}{h_{\beta,K} |\vec{\beta} \cdot \vec{n}|}.
\]

Then
\[
a_h((u_h, \phi_h), v_h) = \sum_{K \in \mathcal{T}_h} \| u_h - U_p \phi_h \|_K^2 + \| \phi_h - Q_p \phi_h \|_K^2 \frac{1}{h_{\beta,K}}
\]
\[
= \| (u_h, \phi_h) \|_h \| v_h \|_h.
\]
This proves the inf-sup condition.

The proof of the continuity inequality also follows from (34) after applying the Cauchy-Schwarz inequality.

The error estimate then immediately follows from Theorem 1.1. \(\square\)

The above analysis is in the most “natural” norms suggested by the method itself. In fact, we have shown above that
\[
\sup_{v_h \in V_h} \frac{a_h((u_h, \phi_h), v_h)}{\| v_h \|_h} = \| (u_h, \phi_h) \|_h,
\]
for all \(u_h \in W_h, \phi_h \in M_h\). Nonetheless, convergence rates in standard norms (like \(L^2\)) are not obvious from the theorem. The remainder of this section is devoted to obtaining convergence rates in \(L^2\)-like norms.

### 3.4. A Poincaré inequality

As a first step to obtain stability and error estimates in \(L^2\)-norm, we prove a Poincaré inequality. Notice that the norm in (31) is applied to the difference \(\psi|_{\partial_{\text{out}K}} - Q_p(\psi|_{\partial_{\text{out}K}})\). This is the difference between the outflow values of \(\psi\) and its inflow values transported onto \(\partial_{\text{out}K}\). Discrete analogues of the Poincaré inequality bound \(L^2\)-like norms using sum of squares of differences (under some discrete analogue of a zero boundary condition). Therefore, it is perhaps not surprising that such a discrete Poincaré type estimate can also be found for the norm in (31) (recalling that any \(\psi\) in \(M_h\) satisfies a zero boundary condition on the inflow boundary).

To establish the inequality, we first need to define “layers” of mesh elements marching from \(\partial_{\text{in}}\Omega\). The first layer is defined by
\[
\mathcal{S}_0 = \{ K \in \mathcal{T}_h : \partial_{\text{in}}K \subseteq \partial_{\text{in}}\Omega \}.
\]
By Lemma 3.1, \( S_0 \) is not empty. Next, setting \( \mathcal{S}_h(0) = \mathcal{S}_h \), we recursively define, for all integers \( \ell > 0 \), the sets

\[
\mathcal{S}_h(\ell) = \mathcal{S}_h(\ell-1) \setminus \mathcal{S}_{\ell-1}
\]

\[
\mathcal{S}_\ell = \{ K \in \mathcal{S}_h(\ell) : \partial_{in} K \subseteq \partial_{in} \Omega(\ell) \},
\]

where \( \Omega(\ell) \) is the domain formed by the union of all triangles of \( \mathcal{S}_h(\ell) \). Repeated application of Lemma 3.1 shows that \( \mathcal{S}_\ell \) is nonempty for every \( \ell \), unless \( \mathcal{S}_h(\ell) \) is empty. So this process exhausts all elements of the mesh, at some finite value of \( \ell \), say \( \ell = n \). The domain \( \Lambda_\ell \defeq \Omega \setminus \Omega(n) \) is meshed by \( \mathcal{S}_0 \cup \mathcal{S}_1 \cdots \cup \mathcal{S}_\ell \). Its outflow boundary is denoted by

\[
\Gamma_\ell = \partial_{out} \Lambda_\ell.
\]

All mesh edges, excluding those on \( \partial_{in} \Omega \), and excluding those where \( \vec{\beta} \cdot \vec{n} = 0 \), are contained in \( \Gamma_\ell \) for some \( \ell \leq n \). With these notations and observations, we impose a mild assumption on the mesh and prove the Poincaré inequality.

**Assumption 3.1.** Define the layer width by

\[
d_\ell = \max\{ h_{\beta,K} : K \in \mathcal{S}_\ell \}.
\]

We assume that our meshes are such that

\[
\sum_{\ell=0}^{n} d_\ell \leq L_\Omega
\]

where \( L_\Omega \) is a fixed constant depending on \( \Omega \), but independent of the meshes and element sizes. We also assume that there is a fixed constant \( C_1 \) such that if \( K \) and \( K' \) are any two
neighboring elements, then either the inequality
\[ h_{\beta,K'} \leq C_1 h_{\beta,K} \]
holds or it holds after exchanging \( K \) and \( K' \).

Above and in the remainder, the letter \( C \), with or without subscripts, denotes generic constants independent of elements \( K \) and polynomial degree \( p \). Their value at different occurrences may vary.

Assumption 3.1 permits quite general meshes, including anisotropic refinements (e.g., to capture shock waves). Loosely speaking, the first part assumes that elements within each layer have about the same length in the flow direction. The second part assumes that element lengths in the flow direction for neighboring elements are comparable. Quasiuniform meshes obviously satisfy the assumption.

**Theorem 3.2.** If Assumption 3.1 holds, then for all \( \psi \in M_h \), we have
\[ \| \psi \|_{\mathcal{h}_{\beta} \mathcal{T}_h}^2 \leq C_0 L^2 \| \psi \|_{\mathcal{h}_{\beta} \mathcal{T}_h}^2 \]
(where \( C_0 \) is independent of \( \mathcal{T}_h \) and \( p \), and the norms are as in (29) and (31)).

**Proof.** The first step is a local inequality. On any triangle \( K \),
\[ \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} \leq \| \psi - Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} + \| Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} \]
\[ \leq \| \psi - Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} + \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K}, \]
where the last inequality was due to Theorem 2.2 (21). Consequently,
\[ \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K}^2 - \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K}^2 \leq (\| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} + \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K}) \| \psi - Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} \]  \hspace{1cm} (35)
holds on every mesh element \( K \).

The next step is to sum over \( \mathcal{R}_E = \mathcal{R}_0 \cup \mathcal{R}_1 \cdots \cup \mathcal{R}_E \). Then, we have
\[ \sum_{K \in \mathcal{R}_E} \left( \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K}^2 - \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K}^2 \right) \leq \sum_{K \in \mathcal{R}_E} \left( \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} + \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K} \right) \| \psi - Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} \]
When rewriting the left hand side as a sum over the mesh edges, we observe that all contributions due to edges interior to \( \Lambda_{\ell} \) cancel out. Furthermore, since \( \psi \in M_h \), it vanishes on the inflow boundary \( \partial_{\text{in}} \Lambda_{\ell} \subseteq \partial_{\text{in}} \Omega \). Therefore only contributions on the outflow boundary of \( \Lambda_{\ell} \), namely \( \Gamma_{\ell} \), remains, i.e.,
\[ \| \psi \|_{\mathcal{h}_{\beta} \Gamma_{\ell}}^2 \leq \sum_{K \in \mathcal{R}_E} \left( \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} + \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K} \right) \| \psi - Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} \]  \hspace{1cm} (36)
We apply Cauchy-Schwarz inequality to the right hand side of (36) to get
\[ \| \psi \|_{\mathcal{h}_{\beta} \Gamma_{\ell}}^2 \leq \left( \sum_{K \in \mathcal{R}_E} 2 h_{\beta,K} \left( \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K} + \| \psi \|_{\mathcal{h}_{\beta} \partial_{\text{in}} K} \right) \right)^{1/2} \left( \sum_{K \in \mathcal{R}_E} \frac{1}{h_{\beta,K}} \| \psi - Q_p \psi \|_{\mathcal{h}_{\beta} \partial_{\text{out}} K}^2 \right)^{1/2} \]
By Assumption 3.1, the lengths \( h_{\beta,K} \) for neighboring elements are comparable, so that
\[ \sum_{K \in \mathcal{R}_E} h_{\beta,K} \| \psi \|^2_{\mathcal{h}_{\beta} \partial_{\text{in}} K} \leq C \sum_{K \in \mathcal{R}_E} h_{\beta,K} \| \psi \|^2_{\mathcal{h}_{\beta} \partial_{\text{out}} K} \]
which implies
\[ \| \psi \|_{2, \mathcal{F}_\ell} \leq C \left( \sum_{K \in \mathcal{K}_\ell} h_{\beta,K} \| \psi \|_{1, \partial_{\text{out}} K} \right)^{1/2} \left( \sum_{K \in \mathcal{K}_\ell} \frac{1}{h_{\beta,K}} \| \psi - \Omega P \psi \|_{2, \partial_{\text{out}} K} \right)^{1/2} \]
\[ = C \| \psi \|_{h, 1/2, \mathcal{R}_\ell} \| \psi \|_{1/2, \mathcal{F}_\ell}. \]

The final step involves multiplying by the layer width \( d_\ell \), and summing over \( \ell \),
\[ \sum_{\ell=0}^n d_\ell \| \psi \|_{2, \mathcal{F}_\ell} \leq \sum_{\ell=0}^n d_\ell C \| \psi \|_{h, 1/2, \mathcal{R}_\ell} \| \psi \|_{1/2, \mathcal{F}_\ell} \]
\[ \leq C L_\Omega \| \psi \|_{h, 1/2, \mathcal{T}_h} \| \psi \|_{1/2, \mathcal{F}_h}, \quad (37) \]
where we increased the norms over \( \mathcal{R}_\ell \) to norms over the whole mesh \( \mathcal{T}_h \). By the definition of \( d_\ell \), we know that
\[ h_{\beta,K} \leq d_\ell, \quad \text{for all } K \in \mathcal{S}_\ell, \]
so we have
\[ \| \psi \|_{h, 1/2, \mathcal{F}_h} = \sum_{\ell=0}^n \sum_{K \in \mathcal{S}_\ell} h_{\beta,K} \| \psi \|_{2, \partial_{\text{out}} K} \leq \sum_{\ell=0}^n \sum_{K \in \mathcal{S}_\ell} d_\ell \| \psi \|_{2, \partial_{\text{out}} K} \]
\[ \leq L_\Omega C \| \psi \|_{h, 1/2, \mathcal{F}_h} \| \psi \|_{1/2, \mathcal{F}_h}, \]
where the last inequality is due to (37). This proves the result. \( \square \)

### 3.5. \( L^2 \)-error estimates

Now we prove an optimal error estimate for \( u_h \) in the standard \( L^2(\Omega) \)-norm, as well as error estimates for the outflux approximation \( \phi_h \) in \( L^2 \)-like norms on mesh edges. The estimates are with constants independent of the polynomial degree \( p \) and mesh \( \mathcal{T}_h \).

**Theorem 3.3.** Suppose \( (u, \phi) \) is the exact solution, \( (u_h, \phi_h) \) is the discrete solution. Then we have the following error estimates:
\[ \| \phi - \phi_h \|_{h, 1/2, \mathcal{F}_h} \leq 3 \inf_{\psi_{p+1} \in M_h} \frac{1}{h_{\beta,K}} \| \phi - \psi_{p+1} \|_{1/2, \partial K}. \quad (38) \]

If Assumption 3.1 holds, letting
\[ \epsilon(\phi) \overset{\text{def}}{=} \inf_{\psi_h \in M_h} \left( \| \phi - \psi_h \|_{h, 1/2, \mathcal{F}_h} + C_0 L_\Omega^2 \| \phi - \psi_h \|_{1/2, \mathcal{F}_h} \right), \]
we have
\[ \| \phi - \phi_h \|_{h, 1/2, \mathcal{F}_h} \leq 2 \epsilon(\phi) \quad \text{and} \]
\[ \| u - u_h \|_\Omega \leq \frac{4}{|\beta|} \epsilon(\phi) + 2 \inf_{w_h \in W_h} \| u - w_h \|_\Omega. \quad (40) \]

**Proof.** The first step of this proof consists of identifying the equations satisfied by the following discrete error functions:
\[ \varepsilon_h^u = \Pi_{\mathcal{W}} u - u_h, \quad \varepsilon_h^\phi = \Pi_M \phi - \phi_h, \]
where \( \Pi_w \) and \( \Pi_M \) are \( L^2 \)-orthogonal projections into \( W_h \) and \( M_h \), respectively. Subtracting the exact and discrete equations,

\[
0 = \sum_{K \in \mathcal{T}_h} \left( - (u - u_h, \mathbf{\bar{\nabla}} \cdot v_h)_K + \langle \phi - \phi_h, v_h \rangle_{\partial \Omega^+ K} - \langle \phi - \phi_h, v_h \rangle_{\partial \Omega^- K} \right)
\]

\[
= \sum_{K \in \mathcal{T}_h} \left( - (\Pi_w u - u_h, \mathbf{\bar{\nabla}} \cdot v_h)_K + \langle \Pi_M \phi - \phi_h, v_h \rangle_{\partial \Omega^+ K} - \langle \phi - \phi_h, v_h \rangle_{\partial \Omega^- K} \right).
\]

where the introduction of \( \Pi_w \) is possible as \( \mathbf{\bar{\nabla}} \cdot \mathbf{v} \) maps \( V_p(K) \) into \( P_p(K) \). Notice that in the last term we may not replace \( \phi \) by \( \Pi_M \phi \) as the inflow traces of \( v_h \) need not be polynomial. But we may add and subtract \( \Pi_M \phi \) within it. Then, we can express this using the discrete error functions as follows:

\[
a_h((\varepsilon_h^u, \varepsilon_h^p), v_h) = \sum_{K \in \mathcal{T}_h} \langle \phi - \Pi_M \phi, v_h \rangle_{\partial \Omega^+ K},
\]

or equivalently (see (34)),

\[
- (\varepsilon_h^u - \Pi_p \varepsilon_h^p, \mathbf{\bar{\nabla}} \cdot v_h)_K + \langle \varepsilon_h^p - \Pi_p \varepsilon_h^p, v_h \rangle_{\partial \Omega^+ K} = \langle \phi - \Pi_M \phi, v_h \rangle_{\partial \Omega^+ K},
\]

(41)

on every mesh element \( K \). In other words,

\[
\varepsilon_h^u - \Pi_p \varepsilon_h^p = \Pi_p (\phi - \Pi_M \phi),
\]

(42a)

\[
\varepsilon_h^p - \Pi_p \varepsilon_h^p = \Pi_p (\phi - \Pi_M \phi).
\]

(42b)

We use these identities to bound the errors. The second step of this proof involves bounding \( \varepsilon_h^p \). By (42b),

\[
\left\| \varepsilon_h^p - \Pi_p \varepsilon_h^p \right\|_{\frac{1}{2}, \partial \Omega^+ K} = \left\| \Pi_p (\phi - \Pi_M \phi) \right\|_{\frac{1}{2}, \partial \Omega^+ K} \leq \left\| \phi - \Pi_M \phi \right\|_{\frac{1}{2}, \partial \Omega^+ K},
\]

(43)

by the bound (21) on \( \Pi_p (\cdot) \) of Theorem 2.2. Therefore,

\[
\left\| \phi - \phi_h \right\|_{\mathbf{H}^1(K)} \leq \left\| \phi - \Pi_M \phi \right\|_{\mathbf{H}^1(K)} + \left\| \varepsilon_h^p \right\|_{\mathbf{H}^1(K)}
\]

\[
= h^{-1/2}_\beta \left\| (\phi - \Pi_M \phi) - \Pi_p (\phi - \Pi_M \phi) \right\|_{\mathbf{H}^1(K)} + h^{-1/2}_\beta \left\| \varepsilon_h - \Pi_p \varepsilon_h^p \right\|_{\mathbf{H}^1(K)}
\]

\[
\leq h^{-1/2}_\beta \left\| \phi - \Pi_M \phi \right\|_{\mathbf{H}^1(K)} + 2h^{-1/2}_\beta \left\| \phi - \Pi_M \phi \right\|_{\mathbf{H}^1(K)}
\]

By the inequality of arithmetic and geometric means, this implies

\[
\left\| \phi - \phi_h \right\|_{\mathbf{H}^1(K)} \leq 3h^{-1}_\beta \left\| \phi - \Pi_M \phi \right\|_{\mathbf{H}^1(K)}
\]

which gives the first error estimate of the theorem. The third step again involves a bound on \( \varepsilon_h^p \), but now in a weaker norm. We use the Poincaré inequality of Theorem 3.2:

\[
\left\| \varepsilon_h^p \right\|_{\mathbf{H}^1(K)} \leq C_0 L^2 \left\| \varepsilon_h^p \right\|_{\mathbf{H}^1(K)} \leq C_0 L^2 \sum_{K \in \mathcal{T}_h} \frac{1}{h^p_{\beta, K}} \left\| \phi - \Pi_M \phi \right\|_{\mathbf{H}^1(K)},
\]

(44)

where we have also used (43) in the last step. Splitting \( \phi - \phi_h = (\phi - \Pi_M \phi) + \varepsilon_h^p \) as before, and estimating, we prove the second estimate (39) of the theorem.
Now we come to the final step, where we obtain the error estimate for $u_h$, namely (40), as follows:

$$
\|\varepsilon_u^u\|_K - \|U_p\varepsilon^\phi\|_K \leq \|\varepsilon_u^u - U_p\varepsilon^\phi\|_K
$$

by triangle inequality

$$
= \|U_p(\phi - \Pi_M\phi)\|_K
$$

by (42a)

$$
\leq \frac{h^{1/2}}{\|\beta\|^{1/2}} \|\phi - \Pi_M\phi\|_{\beta,\partial_h K}
$$

by Theorem 2.2.

Using Theorem 2.2 again, we have

$$
\|\varepsilon_u^u\|_K \leq \frac{h^{1/2}}{\|\beta\|^{1/2}} (\|\varepsilon_u^\phi\|_{\beta,\partial_h K} + \|\phi - \Pi_M\phi\|_{\beta,\partial_h K}).
$$

Summing over all elements and using (44), we obtain

$$
\|\varepsilon_u^u\|_\Omega \leq \frac{2}{\|\beta\|} (\|\varepsilon_u^\phi\|_{h,\partial_h K} + \sum_{K \in \mathcal{T}_h} h_{\beta,K} \|\phi - \Pi_M\phi\|_{\beta,\partial_h K})
$$

$$
\leq \frac{2}{\|\beta\|} \sum_{K \in \mathcal{T}_h} \left( C_0 L_\Omega \|\phi - \Pi_M\phi\|_{\beta,\partial_h K} + h_{\beta,K} \|\phi - \Pi_M\phi\|_{\beta,\partial_h K} \right)
$$

from which the estimate (40) follows. \hfill \Box

3.6. Interior fluxes by postprocessing. The advective flux is $\vec{q} = \vec{\beta} u$. A natural approximation to this is $\tilde{q}_h = \vec{\beta} u_h$, where $u_h$ is the computed solution. However $\tilde{q}_h$ is not conservative. It is possible to easily adapt an idea of [4] to generate a conservative flux by a simple postprocessing scheme.

Our postprocessed flux is denoted by $\vec{q}_h$. Its restriction to each element $K$ lies in the Raviart-Thomas space $P_{p+1}(K) + \bar{x}P_{p+1}(K)$ and is defined by

$$
(q_h, r)_K = - (\vec{\beta} u_h, r)_K, \quad \forall r \in P_p(K),
$$

$$
(q_h \cdot \vec{n}, \mu)_F = (\vec{\varphi}_h, \mu \vec{n})_F, \quad \forall \mu \in P_{p+1}(F),
$$

where (45b) is imposed on all edges $F$ of $K$,

$$
\vec{\varphi}_h = \begin{cases} 
\phi_h \vec{n}, & \text{on } \partial_{out} K, \\
-\phi_h \vec{n}, & \text{on } \partial_{in} K \setminus \partial_{in} \Omega, \\
\vec{\beta} g, & \text{on } \partial_{in} K \cap \partial_{in} \Omega, \\
0, & \text{on faces where } \vec{\beta} \cdot \vec{n} = 0,
\end{cases}
$$

and, as before, $\vec{n}$ denotes the unit outward normal of $K$. Since (45) uses the well known degrees of freedom of the Raviart-Thomas space, it is easy to see that (45) uniquely defines a $\vec{q}_h$ in $H(div, \Omega)$.

**Theorem 3.4.** Write $u_\beta \overset{\text{def}}{=} \vec{\beta} \cdot \nabla u = \nabla \cdot \vec{q}$ and $u_{\beta,h} \overset{\text{def}}{=} \nabla \cdot \vec{q}_h$. Then, $\vec{q}_h$ is conservative, and

$$
u_{\beta,h} - \Pi_{p+1} u_\beta = 0
$$

where $\Pi_{p+1}$ is the $L^2(K)$-orthogonal projection on $P_{p+1}(K)$. 

Proof. First of all, observe that $P_{p+1}(K) \subseteq V_p(K)$. Indeed, if $z_{p+1}$ is any polynomial in $P_{p+1}(K)$, then finding a $v$ in $V_p(K)$ as in Lemma 2.1 such that

$$\bar{\beta} \cdot \vec{\nabla} v = \bar{\beta} \cdot \vec{\nabla} z_{p+1},$$

(47a)

$$v|_{\partial_{\text{out}}K} = z_{p+1}|_{\partial_{\text{out}}K},$$

(47b)

we find from (47a) that $z_{p+1} - v$ must be a function that is constant along the $\bar{\beta}$-direction. But the same function vanishes on $\partial_{\text{out}}K$ by (47b), so it must vanish everywhere. Hence $z_{p+1} \equiv v \in V_p(K)$.

As a consequence, we have, for all $z$ in $P_{p+1}(K)$,

$$\langle \vec{q}_h, \vec{\nabla} z \rangle_K + \langle \vec{q}_h \cdot \vec{n}, z \rangle_{\partial K} = -\langle u_h, \bar{\beta} \cdot \vec{\nabla} z \rangle_K + \langle \phi_h, z \rangle_{\partial_{\text{out}}K} - \langle \phi_h, z \rangle_{\partial_{\text{in}}K}$$

$$+ \langle \bar{\beta} \cdot \vec{n} g, z \rangle_{\partial_h K \cap \partial_{\Omega}}$$

$$= (f, z)_K = (\bar{\beta} \cdot \vec{\nabla} u, z)_K$$

by (45),

$$= (\nabla \cdot \vec{q}, z)_K$$

by (25).

With $\vec{q} = \bar{\beta} u$, we can rewrite this as

$$\langle \nabla \cdot \vec{q}_h, z \rangle_K = (\nabla \cdot \vec{q}, z), \quad \text{for all } z \in P_{p+1}(K),$$

(48)

which proves (46).

To show that $\vec{q}_h$ is conservative, let $D$ be any subdomain formed by a union of some or all of the mesh elements. Then (48) applied with $z = 1$ implies

$$\int_{\partial D} \vec{q}_h \cdot \vec{n} \, ds = \int_{\partial D} \vec{q} \cdot \vec{n} \, ds,$$

where we have also used the $H(\text{div}, \Omega)$-conformity of $\vec{q}_h$. This shows that the net outward fluxes of $\vec{q}_h$ and $\vec{q}$ coincide on any such subdomain $D$. □

4. Numerical studies

We present a few small scale numerical studies to illustrate and confirm the theory. For more realistic and larger size simulations, we will need full $hp$ adaptivity, which will be presented elsewhere.

4.1. Implementation aspects. In comparison with the UDG method, we do have more equations to solve. However, the reason our method remains competitive is that we are able to solve for the fluxes ($\phi_h$) first and locally recover $u_h$ afterwards. This results in a dimensional reduction that is quite attractive for high $p$. Indeed, with respect to $p$, the number of degrees of freedom for $\phi_h$ is $O(p)$, while the corresponding number for $u_h$ is $O(p^2)$. This dimensional reduction is quite analogous to hybridized methods [5], where the so-called Lagrange multipliers are solved for first, and the remaining variables are recovered locally, element by element.

To state the matrix form of the method, we need bases for $W_h$, $M_h$, and $V_h$. For $M_h$, we set a basis consisting of functions supported only on one edge, while the bases for the other spaces consist of functions supported on only one triangle. Let $\Phi$ and $U$ denote the vector of coefficients of $\phi_h$ and $u_h$ in their basis expansion, respectively. To show how one solves for fluxes first, observe that the global finite element space $V_h$ can be split into the outflow extensions $E_{\text{out}}(M_h)$ plus a linearly independent remainder $R_h$. We enumerate the global
basis for $V_h$ such that the basis functions in $E_{\text{out}}(M_h)$ come first. With $v_h$ set to such test functions, (25) reduces to an equation involving only $\phi_h$:

$$\sum_{K \in \mathcal{T}_h} \left( \langle \phi_h, v_h \rangle \partial_{\text{out}} K - \langle \phi_h, v_h \rangle \partial_{\text{in}} K \right) = (f, v_h)_{\Omega} - \langle \vec{\beta} \cdot \vec{n} g, v_h \rangle_{\partial_{\text{in}} \Omega}$$

(49)

for all $v_h \in E_{\text{out}}(M_h)$. As a consequence, the matrix of (25) is block triangular:

$$\begin{pmatrix} A & 0 \\ B & C \end{pmatrix} \begin{pmatrix} \Phi \\ U \end{pmatrix} = F$$

(50)

where $A$, $B$ and $C$ are sparse matrix blocks, and $F$ is the corresponding load vector. This clearly shows that we can solve for $\Phi$ first and the result can then be used to compute $u_h$ (or $U$) locally, element by element.

Additionally, note that in the decomposition $V_h = E_{\text{out}}(M_h) \oplus R_h$, all the functions in $V_h$ having discontinuities inside elements lie in the $E_{\text{out}}(M_h)$-component. Therefore, when making the stiffness matrix of the bilinear form $a_h((u_h, \phi_h), v_h)$, there is no need to integrate basis functions with discontinuities within the element. Indeed, as seen in (49), the term involving integration within elements, namely $(u_h, \vec{\beta} \cdot \vec{\nabla} v_h)$, vanishes for $v_h$ in $E_{\text{out}}(M_h)$, so there is no need to compute this integral.

Finally, suppose we enumerate the basis for $M_h$ in such a way that functions on $\Gamma_{\ell-1}$ appear before those on $\Gamma_{\ell}$ (see the definition of the layers in §3.4). Then the matrix $A$ in (50) is a square triangular matrix. In this case, $\Phi$ can be found fast using backsubstitution. Since this is the only globally coupled system to solve, the remaining (local) computations for $u_h$ can be locally optimized (or parallelized).

4.2. A one-dimensional example. We begin with a simple one-dimensional example to show the enhanced accuracy and stability of the DPG method compared to the DG method.

**Figure 3.** Convergence for the one-dimensional example
The model problem on $\Omega = (0, 1)$ that we shall consider is

$$u' = f, \quad u(0) = u_0,$$

with data $u_0 \in \mathbb{R}$ and $f \in L^2(0, 1)$ set so that the exact solution is

$$u(x) = \arctan(\alpha(x - x_0))$$

where $x_0 = 1$ and $\alpha = 100$. We use the analogue of our spectral DPG method (of Section 2) in one dimension, i.e., $K = (0, 1)$ and the test space is $V_p(K) = P_{p+1}(K)$.

Figure 4.2 shows the error in $u$ vs. $p$ in a semilog plot. While both methods exhibit exponential convergence, the error for the DPG method is one order less than that for the DG method. The gap between the two convergence curves grows with increasing coefficient $\alpha$ that controls the “steepness” of the solution.

The different behavior of the two methods is further illustrated in Figures 4(a) and 4(b) that show the graphs of the approximate solutions for some values of $p$. Both methods deliver the exact value of the flux at $x = 1$. Contrary to the DG method, however, the DPG solution $u$ within the element is “disconnected” from value at 1 and delivers the best approximation error in $L^2$-norm. This manifests itself with a less oscillatory behavior of the solution. Our numerics also confirmed Theorem 2.1, i.e., when we compared the DPG solution with with the $L^2$-projection of the exact solution, we found the difference to be zero (of the order of round-off errors).

4.3. $h$ and $p$ convergence to a solution with discontinuity. Following [7], we consider a square domain $\Omega = (-1, 1)^2$ wherein an advection problem is set up so that $\beta = (1, 9/10)$ and the exact solution is

$$u(x, y) = \begin{cases} 
\sin(\pi(x + 1)^2)/4\sin(\pi(y - 9x/10)/2) & \text{for } -1 \leq x \leq 1, 9x/10 < y < 1, \\
\exp(-5(x^2 + (y-9x/10)^2)) & \text{for } -1 \leq x \leq 1, -1 \leq y < 9x/10.
\end{cases}$$
This $u$ has a discontinuity along the line $y = 9x/10$. As in [7], we first mesh $\Omega$ by an $n \times n$ quadrilateral mesh aligned with the line of discontinuity (see [7, Fig. 10] for details). Since our method is based on triangular meshes ([7] only considered quadrilateral meshes), we further split each of the quadrilaterals into two triangles by connecting their diagonals of positive slope. Another difference with the experiment in [7] is that while [7] needed to include a lower order reaction term for theoretical reasons, we do not need to, hence we solve the purely advective problem. We report the errors in $u_h$ and $\phi_h$ for the cases $n = 5, 9, 17, 33$ and $p = 1, \ldots, 5$ in Figure 5.

It is clear from Figure 5 that the DPG method converged under $h$ and $p$ refinements as if the solution were infinitely regular (see Figure 5). We observed a similar behavior for the DG method as well. Such observations demonstrate the advantage of using discontinuous finite elements aligned with the solution discontinuity (in contrast to streamline diffusion based methods – see [7] for comparison of DG with streamline diffusion). The errors observed for the DG method (not shown in the figure), as in § 4.2, remained higher than that of the DPG method. Figure 5 suggests that exponential rates of convergence can be obtained with the DPG method, even for discontinuous solutions, once an adaptive strategy to align the meshes with the shocks is implemented.

The data that was used to plot Figure 5 also shows the rate of the convergence. Figure 5(a) indicate that $\|u - u_h\|$ converges at the rate $h^{p+1}$ (for $p = 1 \ldots 5$). This is in accordance with Theorem 3.3. On the other hand, the fluxes converge such that $\|\phi - \phi_h\|_{h^{\frac{1}{2}}}$ goes to zero at the rate of $h^{p+2.5}$, which is one order more than what we were able to prove in Theorem 3.3.

4.4. Peterson example. Next, we consider the well-known Peterson example [12]. Peterson’s mesh of the unit square is a specific quasiuniform mesh of the type appearing in Figure 7, obtained from an $n \times n$ partition of the unit square, but with additional vertical lines through some mesh vertices such that the new lines divide the unit square into, say $m$, vertical strips (see [12] for details). On such meshes, we apply the UDG and DPG method to the problem $\partial u/\partial y = 0, u(x, 0) = \sin 6x, x \in (0, 1)$. The results in Figure 6 show that
the DPG method delivers better results than the standard DG method. Figure 6(a) is obtained with $p = 1$ and four progressively finer meshes: first with $n = 6, m = 3$, second with $n = 12, m = 6$, third with $n = 24, m = 8$, and fourth with $n = 48, m = 16$. This allows us to study the case of $h$-refinement. On the other hand, Figure 6(b) is obtained by fixing the mesh with $n = 6, m = 3$, and increasing the degree $p$ from 0 through 5. The results clearly demonstrate the well-known 0.5-order suboptimality of the DG method in the $h$-refinement case, but more interestingly, also show that the DPG method converges at the optimal rate.

We also present the solutions $u_h$ obtained with both DG and DPG methods when the inflow data is $u(x, 0) = x^2$ in Fig. 7. We used piecewise constant approximations ($p = 0$). Observe that as the flow proceeds upwards, the values ‘diffuse’ horizontally for DG case, while there is little indication of such crosswind diffusion for the DPG method with the optimal test functions.

5. Concluding remarks

5.1. Summary. We proved optimal error estimates for $u_h$ in $h$ and $p$. Using the known best approximation estimates [15] for a quasiuniform mesh of meshsize $h$, we obtain as a corollary of Theorem 3.3 that

$$C\|u - u_h\|_\Omega \leq \frac{h^{s_1}}{p^{s_1}} |u|_{H^{s_1}(\Omega)} + \left( \frac{1}{|\beta| h^{1/2}} \right) \frac{h^{s_2-1/2}}{p^{s_2-1/2}} |u|_{H^{s_2}(\Omega)}$$

with some $C$ independent of $h$ and $p$ and any $0 \leq s_1 \leq p + 1$ and $0 \leq s_2 \leq p + 2$. If the solution is smooth, choosing $s_1 = p + 1$ and $s_2 = p + 2$, we obtain the optimal $h$-convergence rate of $O(h^{p+1})$. The $p$-convergence rate is also optimal.

In every numerical experiment we performed, without exception, the DPG method gave more accurate solutions than the standard DG method. Numerical experiments confirm...
the theoretically proved optimal rate of convergence for the primal variable $u_h$. For the fluxes, we proved a rate of convergence that is suboptimal by one order, but numerical experiments indicate that the fluxes do converge at optimal order.

Of course, the full potential of the method is not indicated by an estimate like (51). Indeed, one can achieve exponential rate of convergence by constructing a variable-degree analogue where each element $K$ is endowed with its own trial space of degree $p_K$. The fluxes must be chosen to be of degree one plus the maximum of the degrees from adjacent elements. A full study of the variable degree version, together with an $hp$-adaptive scheme which automatically selects $h$ or $p$ refinement in different locations, is postponed to a future work.

5.2. The three-dimensional case. The entire analysis of Section 2 holds in any dimension, including three. The sole reason we restricted ourselves to the two-dimensional case in Section 3 is that Lemma 3.1 does not hold for general tetrahedral meshes. This fact does not seem to be well known, so we indicate a counterexample in Figure 8. In the mesh shown therein, there is no tetrahedron whose inflow boundary is wholly contained in the global inflow boundary of the domain.

In situations like in Figure 8, we may choose to appropriately bisect the ‘problematic’ tetrahedra so that Lemma 3.1 does hold at each stage. Alternatively, while generating tetrahedral meshes by advancing front meshing algorithms, we can ensure that elements at each front are such that Lemma 3.1 is satisfied. Notice that Lemma 3.1 is required not only for the analysis of our method, but also for practical implementation. Indeed, the process of splitting the mesh into layers $\mathcal{S}_\ell$ (see § 3.4) yields an enumeration of flux degrees of freedom that makes the matrix for $\phi_h$’s triangular, and hence suitable for fast solution by backsubstitution. Therefore any extra effort to obtain meshes of the required type is likely to pay off in the final analysis. (Note that Lemma 3.1 is needed to obtain triangular matrices even when using the standard UDG method.) These and related algorithmic issues will be studied in the future.

5.3. Further studies. We outline a few directions in which we are pursuing further studies. The singularly perturbed convection-diffusion problem is of great interest. It is easy
to formulate a generalization of our method by combining with the mixed method. This is because the space for $u_h$ in our method and in the mixed method is the same (one can proceed, for instance, along the same lines as in [6]). However, proving $hp$ estimates with $p$ independent constants for such a method does not appear to be an easy task.

The case of variable transport direction $\vec{\beta}$ can be handled by projecting $\vec{\beta}$ into an appropriate finite element space. In particular, a low order method can be immediately written down if we approximate $\vec{\beta}$ by its lowest-order Raviart-Thomas interpolant $\Pi_h^{RT} \vec{\beta}$. Then, whenever $\nabla \cdot \vec{\beta} = 0$, the approximant $\Pi_h^{RT} \vec{\beta}$ is a piecewise constant vector field with continuous interelement normal components. Hence, by simply modifying our test space $V_p(K)$ to align with $\Pi_h^{RT} \vec{\beta}$ within each element $K$, we obtain a low-order generalization of the DPG method to the case of variable $\vec{\beta}$ with minimal modifications. To obtain truly high-order methods for variable $\vec{\beta}$, our test space must take into account the variable advection.

This and other generalizations become clearer, once we view the method presented here as a particular case of a more general paradigm for constructing schemes, not only for the transport problem or its singular perturbation, but indeed for a much larger class of problems. The new paradigm is to find a space of optimal test functions tailored for any particular problem. It turns out that the framework of DG methods offers a unique opportunity to locally compute test functions that approach optimality in the sense of reproducing the exact stability properties of the boundary value problem at the discrete level. This approach and its connection to the space of test functions presented here will be clarified in a sequel.

**Appendix A. Proof of Theorem 2.2**

This section is devoted to a proof of Theorem 2.2. Before we embark on this, we need to develop several intermediate results. Recall that $\mathcal{E}_{\text{out}}$ denotes the extension from the outflow boundary. Now, let us also define the extension from inflow boundary, denoted by $\mathcal{E}_{\text{in}}$ as follows. Given a function $\mu$ on $\partial_{\text{in}} K$, the function $\mathcal{E}_{\text{in}} \mu$ on $K$ coincides with $\mu$ on $\partial_{\text{in}} K$ and is independent of $\eta_1$ (i.e., it is constant along the $\vec{\beta}$-direction).
Lemma A.1. Suppose $\phi$ in $L^2(\partial_{\text{out}}K)$ and $\mu$ in $L^2(\partial_{\text{in}}K)$. Then

$$ \langle \bar{\beta} \cdot \vec{n} \mathcal{E}_{\text{out}} \phi, \mathcal{E}_{\text{in}} \mu \rangle_{\partial K} = 0. $$

(52)

Moreover, using the norm defined in (20), we have

$$ \| \mathcal{E}_{\text{in}} \phi \|_{\beta, \partial_{\text{in}}K} = \| \phi \|_{\beta, \partial_{\text{out}}K}. $$

(53)

Proof. By integration by parts, we have

$$ \langle \bar{\beta} \cdot \vec{n} \mathcal{E}_{\text{out}} \phi, \mathcal{E}_{\text{in}} \mu \rangle_{\partial K} = (\bar{\beta} \cdot \nabla \mathcal{E}_{\text{out}} \phi, \mathcal{E}_{\text{in}} \mu)_K + (\mathcal{E}_{\text{out}} \phi, \nabla \cdot (\bar{\beta} \mathcal{E}_{\text{in}} \mu))_K, $$

and both terms on the right are zero. This proves (52).

Now let us prove (53). Recall the coordinate system aligned with the flow, defined in (10). Project $K$ onto the $\eta_1 = 0$ hyperplane along the $\bar{\beta}$-direction to obtain a $N - 1$ dimensional domain $D$, meshed with simplices $D_j$ (see Fig. 9) in one less dimension. The flow field $\bar{\beta}$ generates an isomorphism from $D$ onto $\partial_{\text{in}}K$ as well as $\partial_{\text{out}}K$. We denote the former by $\mathcal{F}_{\text{in}}$ and the latter by $\mathcal{F}_{\text{out}}$.

The values of $\mathcal{E}_{\text{in}} \mu$ on $\mathcal{F}_{\text{out}}(D_j)$ are mapped over from $\mathcal{F}_{\text{in}}(D_j)$. Since $\mathcal{F}_{\text{out}}(D_j)$ is mapped to $\mathcal{F}_{\text{in}}(D_j)$ by the map $\mathcal{F}_{\text{in}} \circ \mathcal{F}_{\text{out}}^{-1}$, which is a transformation whose Jacobian is constant on $\mathcal{F}_{\text{out}}(D_j)$, integration via a change of variable shows that

$$ \| \mathcal{E}_{\text{in}} \mu \|^2_{\mathcal{F}_{\text{out}}(D_j)} = \frac{|\mathcal{F}_{\text{out}}(D_j)|}{|\mathcal{F}_{\text{in}}(D_j)|} \| \mu \|^2_{\mathcal{F}_{\text{in}}(D_j)}. $$

(54)

Now, consider the solid $S_j$ formed by the faces $\mathcal{F}_{\text{out}}(D_j)$, $\mathcal{F}_{\text{in}}(D_j)$, filled by line segments parallel to $\bar{\beta}$. Since $\bar{\beta} \cdot \vec{n} = 0$ on all faces of this solid other than $\mathcal{F}_{\text{out}}(D_j)$ and $\mathcal{F}_{\text{in}}(D_j)$, by the divergence theorem, we find that

$$ 0 = \int_{S_j} \nabla \cdot \bar{\beta} \, dx = |\bar{\beta} \cdot \vec{n}_{\mathcal{F}_{\text{out}}(D_j)}| |\mathcal{F}_{\text{out}}(D_j)| + |\bar{\beta} \cdot \vec{n}_{\mathcal{F}_{\text{in}}(D_j)}| |\mathcal{F}_{\text{in}}(D_j)| $$

Using this in (54), we find that

$$ |\bar{\beta} \cdot \vec{n}_{\mathcal{F}_{\text{out}}(D_j)}| \| \mathcal{E}_{\text{in}} \mu \|^2_{\mathcal{F}_{\text{out}}(D_j)} = |\bar{\beta} \cdot \vec{n}_{\mathcal{F}_{\text{in}}(D_j)}| \| \mu \|^2_{\mathcal{F}_{\text{in}}(D_j)}. $$

Summing over all $j$, we obtain (53).

Now, let us define the exact local solution operators, in analogy with the discrete ones in (17). Namely, we define

$$ \mathcal{Q} : L^2(\partial_{\text{in}}K) \longmapsto L^2(\partial_{\text{out}}K), \quad \mathcal{U} : L^2(\partial_{\text{in}}K) \longmapsto L^2(K), $$

as follows: Given $\phi$ in $L^2(\partial_{\text{in}}K)$, the functions $\mathcal{Q}\phi$ and $\mathcal{U}\phi$ are defined by

$$ -(\mathcal{U}\phi, \bar{\beta} \cdot \nabla v)_K + (\mathcal{Q}\phi, v)_{\partial_{\text{out}}K} = (\phi, v)_{\partial_{\text{in}}K}, $$

(55)

for all $v$ in

$$ V(K) \overset{\text{def}}{=} \{ v \in L^2(K) : \beta \cdot \nabla v \in L^2(K) \}. $$

(56)

The next result concerns the operators $\mathcal{Q}$ and $\mathcal{Q}_p$. Recall that $\Pi_h$ denotes the $L^2$-orthogonal projection onto $M_h$ (it obviously acts face by face).
Lemma A.2. Let \( \phi \in L^2(\partial_{\text{out}} K) \). Using the norm defined in (19), we have

\[
\| Q\phi \|_{\beta, \partial_{\text{out}} K} = \| \phi \|_{\beta, \partial_{\text{in}} K}
\]

Furthermore, the operator \( Q_p \) of (17) is related to \( Q \) by

\[
Q_p = \Pi_M Q.
\]

Proof. By (55), we know that

\[
\langle Q\phi, \mu \rangle_{\partial_{\text{out}} K} = \langle \phi, E_{\text{out}} \mu \rangle_{\partial_{\text{in}} K} \quad \forall \mu \in L^2(\partial_{\text{out}} K),
\]

while by (52) of Lemma A.1, we know that

\[
\langle \phi, E_{\text{out}} \mu \rangle_{\partial_{\text{in}} K} = \langle \beta \cdot \vec{n}_{\text{in}}, E_{\text{in}}(\frac{\phi}{\beta \cdot \vec{n}_{\text{in}}}) \rangle_{\partial_{\text{out}} K},
\]

where \( \vec{n}_{\text{in}} \) and \( \vec{n}_{\text{out}} \) denote the unit outward normals on \( \partial_{\text{in}} K \) and \( \partial_{\text{out}} K \), respectively. Combining, we conclude that

\[
\langle Q\phi, \mu \rangle_{\partial_{\text{out}} K} = -\langle \beta \cdot \vec{n}_{\text{out}} E_{\text{in}}(\frac{\phi}{\beta \cdot \vec{n}_{\text{in}}}) \rangle_{\partial_{\text{out}} K}, \quad \forall \mu \in L^2(\partial_{\text{out}} K),
\]

Thus, we find that

\[
Q\phi = -\beta \cdot \vec{n}_{\text{out}} E_{\text{in}}(\frac{\phi}{\beta \cdot \vec{n}_{\text{in}}}).
\]

In view of this, we can use (53) of Lemma A.1 with \( \phi / \beta \cdot \vec{n}_{\text{in}} \) in place of \( \phi \), to get

\[
\sum_{F_{\text{out}} \subseteq \partial_{\text{out}} K} |\beta \cdot \vec{n}_{F_{\text{out}}}| \left\| E_{\text{in}}(\frac{\phi}{\beta \cdot \vec{n}_{\text{in}}}) \right\|_{F_{\text{out}}}^2 = \sum_{F_{\text{in}} \subseteq \partial_{\text{in}} K} |\beta \cdot \vec{n}_{F_{\text{in}}}| \left\| \frac{\phi}{\beta \cdot \vec{n}_{\text{in}}} \right\|_{F_{\text{in}}}^2,
\]

or in other words,

\[
\sum_{F_{\text{out}} \subseteq \partial_{\text{out}} K} \frac{1}{|\beta \cdot \vec{n}_{F_{\text{out}}}|} \left\| Q\phi \right\|_{F_{\text{out}}}^2 = \sum_{F_{\text{in}} \subseteq \partial_{\text{in}} K} \frac{1}{|\beta \cdot \vec{n}_{F_{\text{in}}}|} \left\| \phi \right\|_{F_{\text{in}}}^2.
\]
Thus we have proved (57).

To prove (58), it suffices to observe that on each element, \( Q_p \phi \) is the discrete spectral approximation to the exact solution \( Q \phi \), hence by the superconvergence result of Theorem 2.1, we find that \( Q_p \phi - \Pi_\alpha Q \phi = 0 \).

We need two more lemmas before we proceed to obtain bounds for the local solution operators.

**Lemma A.3.** Suppose \( w \) is in \( P_p(K) \) and \( v \) is the function in \( V_p(K) \) obtained via Lemma 2.1 satisfying

\[
\left. v \right|_{\partial_{\text{out}}K} = 0, \quad \vec{\beta} \cdot \nabla v = w.
\] (59)

Then

\[
\|v\|_{\beta,\partial_{\text{in}}K}^2 \leq \frac{1}{|\beta|} h_{\beta,K} \|w\|_K^2; \tag{60}
\]

\[
\|v\|_K^2 \leq \frac{1}{|\beta|^2} h_{\beta,K}^2 \|w\|_K^2. \tag{61}
\]

**Proof.** We use the notations in the proof of Lemma A.1. Let \( \hat{v} \) denote the function obtained by mapping the values of \( v \left| \partial_{\text{out}}K \right. \) to \( D \), i.e.,

\[
\hat{v}(\eta_2, \ldots, \eta_N) = v(\mathcal{F}_{\text{in}}(0, \eta_2, \ldots, \eta_N)).
\]

Then, since \( |\mathcal{F}_{\text{in}}(D_j)| |\vec{\beta} \cdot \vec{n}_{\mathcal{F}_{\text{in}}(D_j)}| = |D_j| |\vec{\beta}| \), we obtain by a change of variable that

\[
\|v\|_{\mathcal{F}_{\text{in}}(D_j)}^2 = \frac{|\mathcal{F}_{\text{in}}(D_j)|}{|D_j|} \|\hat{v}\|_{D_j}^2 = \frac{|\vec{\beta}|}{|\vec{\beta} \cdot \vec{n}_{\mathcal{F}_{\text{in}}(D_j)}|} \|\hat{v}\|_{D_j}^2. \tag{62}
\]

Now, let \( f_{\text{out}}(\eta_2, \ldots, \eta_N) \) and \( f_{\text{in}}(\eta_2, \ldots, \eta_N) \) denote the \( \eta_1 \)-components of \( \mathcal{F}_{\text{out}}(0, \eta_2, \ldots, \eta_N) \) and \( \mathcal{F}_{\text{in}}(0, \eta_2, \ldots, \eta_N) \), respectively. Then the inflow and outflow boundaries are the graphs of \( f_{\text{in}} \) and \( f_{\text{out}} \), respectively. By (59),

\[
v(\eta_1, \ldots, \eta_N) = \int_{f_{\text{out}}(\eta_2, \ldots, \eta_N)}^{\eta_1} \frac{1}{|\vec{\beta}|} w(s, \eta_2, \ldots, \eta_N) \, ds \tag{63}
\]

When we evaluate this expression on the inflow boundary \( \eta_1 = f_{\text{in}}(\eta_2, \ldots, \eta_N) \), we obtain values of \( \hat{v} \). Consequently, (62) implies that

\[
\|v\|_{\beta,\partial_{\text{in}}K}^2 = \sum_j |\vec{\beta}| \int_{D_j} |\hat{v}|^2 \, d\eta_2 \ldots d\eta_N
\]

\[
= |\vec{\beta}| \int_D \left( \int_{f_{\text{out}}(\eta_2, \ldots, \eta_N)} \frac{1}{|\vec{\beta}|} w(s, \eta_2, \ldots, \eta_N) \, ds \right)^2 \, d\eta_2 \ldots d\eta_N
\]

\[
\leq \frac{1}{|\beta|^2} h_{\beta,K} \int_K |w|^2 \, d\eta_1 \ldots d\eta_N,
\]

and the first estimate of the lemma follows.
For the second estimate, we again use (63).

\[
\|v\|^2_K = \sum_j \int_{f_{\text{out}}(\eta_2, \ldots, \eta_N)} f_{\text{in}}(\eta_2, \ldots, \eta_N) \int_{D_j} \left[ \frac{1}{\beta} w(s, \eta_2, \ldots, \eta_N) ds \right]^2 d\eta_2 \ldots d\eta_N d\eta_1 \\
\leq \int_{f_{\text{out}}(\eta_2, \ldots, \eta_N)} f_{\text{in}}(\eta_2, \ldots, \eta_N) \int_{D_j} \left| \frac{h_{\beta, K}}{\beta} \right|^2 |w(s, \eta_2, \ldots, \eta_N)|^2 ds d\eta_2 \ldots d\eta_N d\eta_1 \\
\leq \frac{h_{\beta, K}^2}{|\beta|^2} \int_K |w(s, \eta_2, \ldots, \eta_N)|^2 ds d\eta_2 \ldots d\eta_N.
\]

This finishes the proof. \(\square\)

**Lemma A.4.** Suppose \(\psi\) is in \(M_{p+1}(\partial_{\text{out}} K)\) and \(v\) is the function in \(V_p(K)\) satisfying

\[
v|_{\partial_{\text{out}} K} = \psi, \quad \vec{\beta} \cdot \nabla v = 0.
\]

Then

\[
\|v\|^2_K \leq \frac{h_{\beta, K}}{|\beta|} \|\psi\|^2_{|\beta|, \partial_{\text{out}} K}.
\]

**Proof.** Map \(\psi\) from \(\partial_{\text{out}} K\) to \(D\) using the flow isomorphism to obtain a function \(\hat{\psi}\) on \(D\). Then, evaluating the norm \(\|v\|^2_K\) as an iterated integral,

\[
\|v\|^2_K = \sum_j \int_{f_{\text{out}}(\eta_2, \ldots, \eta_N)} f_{\text{in}}(\eta_2, \ldots, \eta_N) \int_{D_j} |\hat{\psi}(\eta_2, \ldots, \eta_N)|^2 d\eta_2 \ldots d\eta_N d\eta_1 \quad \text{(by Fubini’s theorem)}
\]

\[
= \sum_j \int_{f_{\text{out}}(\eta_2, \ldots, \eta_N)} f_{\text{in}}(\eta_2, \ldots, \eta_N) \left| \frac{\vec{\beta} \cdot \vec{n}_{\text{out}}(D_j)}{|\vec{\beta}|} \right| \|\psi\|^2_{f_{\text{out}}(D_j)} d\eta_1 \quad \text{(cf. (62))}
\]

\[
\leq \frac{h_{\beta, K}}{|\beta|} \|\psi\|^2_{|\beta|, \partial_{\text{out}} K},
\]

as the maximum value of \(|f_{\text{in}} - f_{\text{out}}|\) is \(h_{\beta, K}\). \(\square\)

**Proof of Theorem 2.2.** To prove the bound on \(Q_p \psi\) in (21), we use Lemma A.2 and the fact that orthogonal projectors have unit norm, so that

\[
\|Q_p \psi\|^2_{|\beta|, \partial_{\text{out}} K} = \sum_{F_{\text{out}} \subseteq \partial_{\text{out}} K} \frac{1}{|\beta \cdot \vec{n}_{\text{out}}|} \|Q_p \psi\|^2_{F_{\text{out}}} = \sum_{F_{\text{out}} \subseteq \partial_{\text{out}} K} \frac{1}{|\beta \cdot \vec{n}_{\text{out}}|} \|I_M Q_p \psi\|^2_{F_{\text{out}}}
\]

\[
\leq \sum_{F_{\text{out}} \subseteq \partial_{\text{out}} K} \frac{1}{|\beta \cdot \vec{n}_{\text{out}}|} \|Q \psi\|^2_{F_{\text{out}}} = \|Q \phi\|^2_{|\beta|, \partial_{\text{out}} K},
\]

and complete using (57).

To prove the bound on \(U_p \phi\), let \(v\) in \(V_p(K)\) be a function as in Lemma A.3 satisfying

\[
v|_{\partial_{\text{out}} K} = 0, \quad \vec{\beta} \cdot \nabla v = U_p \phi.
\]
Substituting this $v$ in the definition (17) of $U_p$, we obtain
\[
\|U_p\phi\|_K^2 = \langle \phi, v \rangle_{\partial u K} \leq \|\phi\|_{\beta, \partial u K} \|v\|_{\beta, \partial u K}
\]
\[
\leq \|\phi\|_{\beta, \partial u K} h^{1/2}_{\beta, K} \|U_p\phi\|_K
\]
by Lemma A.3, so the proof of (21) is finished.

To prove (22), first consider $Q_p^f z$. In its definition, namely in (18), we can set $v$ to be the function given by Lemma A.4 with $\psi = Q_p^f z / |\vec{\beta} \cdot \vec{n}|$. Then
\[
\|Q_p^f z\|_{1/2, \beta, \partial u K} = (z,v) \leq \|z\|_K \|\frac{1}{|\vec{\beta} \cdot \vec{n}|} Q_p^f z\|_{\beta, \partial u K}
\]
\[
= \|z\|_K h^{1/2}_{\beta, K} \|Q_p^f z\|_{1/2, \beta, \partial u K}.
\]

Next, consider $U_p^f z$. In this case, we set $v$ to be the function in $V_p^f(K)$ with $\vec{\beta} \cdot \nabla v = -U_p^f z$ and $v|_{\partial u K} = 0$, given by Lemma A.3. Substituting this $v$ into (18), and applying (61) of Lemma A.3, we have
\[
\|U_p^f z\|_K^2 = (z,v) \leq \|z\|_K \|v\|_K \leq \|z\|_K h^{1/2}_{\beta, K} \|U_p^f z\|_K.
\]

This proves the last estimate of the theorem and finishes the proof. \square
